Title : The Influence of Blood Transfusion and Blood Loss on the  
Secretory Function of the Small Intestine

Orig Pub : Sb. tr. N.-i. in-t pereliyaniya krovi, Georgian SSR, 1957,  
Vol 5, 98-111

Abstract : In dogs with fistulae of the small intestine of the  
Thierry-Vella type, transfusions of homologous blood in  
normal conditions produced, within the first six hours,  
inhibition of secretion, and within the following day, an  
increase in secretion. With acute moderate blood loss,  
especially in the presence of anemia following blood-  
letting, the intestinal secretion diminished. Blood

2096. Optical Investigation of Liquid Helium II. L. W. Schultze and A. K. Kikinis. *Phys. Zeits. d. Sowjetunion*, 10, 1, pp. 119-120, 1936. *In German*.—The optical properties of HeII are briefly stated. When the liquid is cooled from  $4.22^{\circ}$  to  $1.73^{\circ}$  Abs., no rotation of the plane of polarisation can be detected. In an investigation of the Kerr effect at  $1.73^{\circ}$  Abs. and with a constant field of 6900 V/cm. no change in intensity could be detected between crossed nicols. It is concluded that the anisotropy of liquid HeII is less than the accuracy of measurement, and the anomaly of the specific heat cannot be explained on the theory of liquid crystals. E. H. D.

CH Thin films of intermetallic compounds. A. K. Rikomin  
 and G. D. Fedorov. Doklady Akad. Nauk S.S.S.R. 92,  
 1103-5 (1963). --  $Mg_2Si$ , which should be a dielectric, is  
 difficult to prep. stoichiometrically by fusion.  $Mg_2Si$   
 prepd. by simultaneous evapn. of the components on a glass  
 plate *in vacuo*, in films approx. 1000 Å. thick exhibited a  
 narrow transparent strip sharply bounded and lying per-  
 pendicular to a line between the evapn. sources. The posi-  
 tion of the strip corresponded to  $Mg_2Si$  by geometric calcn.  
 The light passing through the strip was 25-49% of that  
 passing through the glass alone. Curves of transmittance vs.  
 distance across the strip showed a slight min. near the middle  
 of the peak. This usually disappeared within several days,  
 but remained for 1.5 months in one case. Prolonged expo-  
 sure of the films to air produced a widening of the trans-  
 parent strip. The Mg side of the strip acquired a stable  
 yellow-brown color (transmitted light). Mg-As, Ca-Bi,  
 and Ca-As produced transparent strips that widened on  
 exposure to the air; the opaque part of the films acquired a  
 bright color (especially for Mg-As). R. D. Misch

**AUTHOR:** LIKHTER, A.I., KIKOIN, A.K.  
**TITLE:** The Influence of Exposure to Radiation by Neutrons on the Compressibility of Metals.  
 (Vliyaniye neytronnogo obluheniya na szhimayemost' metallov. Russian).  
**PERIODICAL:** Zhurnal Eksperim. i Teoret. Fiziki, 1957, Vol 32, Nr 4, pp 945 (U.S.S.R.)  
**ABSTRACT:** First of all, the paper under review gives a brief summary of the present stage reached in the consideration of the above problem. According to the relevant investigations carried out so far, such exposure to radiation has either no effects or only very slight effects.

The authors of the paper under review investigated in a nuclear reactor the influence of the exposure to radiation by fast neutrons with respect to the compressibility of aluminum and magnesium. Because this compressibility is directly connected with the modulus of elasticity and with the modulus of shearing, and because the observations failed to detect any change of these moduli in the substances investigated, it is probable that the compressibility will not undergo any noticeable changes under influence of the exposure to radiation by neutrons. The cylindrical samples of a height of 6 mm and of a diameter of 6 mm were made of technologi-

Card 1/3

56-4-49/52

The Influence of Exposure to Radiation by Neutrons on the Compressibility of Metals.

oally pure electrolytical material. The compressibility was investigated by means of a device for the measurement of the spatial compressibility employing the method of the shift of the piston. A description of this method will be given in another paper. The influence of friction was taken into account by recording the curves of the 'shift of the piston pressure' at decreasing and increasing pressure, and then computing their mean value. The measurements were carried out after having applied pressure to the sample up to a maximum pressure of about 15.000 kg/cm<sup>2</sup>.

The samples were exposed to radiation in a nuclear reactor, and the total current of the neutrons amounted to  $1.07 \cdot 10^{19}$  n/cm<sup>2</sup>. After exposure to radiation, the compressibility was measured under the same conditions as before the exposure to radiation. In this context the measurements, due to the remanent activity of the samples, could be carried out only three days after the exposure to radiation had been terminated. With respect to aluminum and magnesium, the curves of the 'shift of the piston pressure' are completely identical, both before and after the exposure to radiation, i.e. the exposure to radiation does not affect the com-

TITLE: Electric Conductivity of Mg-Bi Alloys (Elektroprovodnost' splavov sistemy Mg-Bi)

PERIODICAL: Tr. Ural'skogo politekhn. in-ta, 1957, Nr 72, pp 76-89

ABSTRACT: An investigation of the relationship between the resistance (R) of thin (1000-angstrom) films of Mg-Bi alloys and the composition; curves of  $\log 1/R = f(1/T)$  were also obtained for a sample having a stoichiometric content of  $Mg_3Bi_2$  (40 atom % Bi) and close to it. The film was made by Vekshinsky's technique of spraying onto a glass plate and was then cut into strips 1-1.5 mm wide. Each strip contained a concentration interval of  $\sim 2$  atom % Bi. 20-25 strips of each film were examined and measurements taken in a vacuum. Curves of the relationship of the R of Mg and Bi to the thickness of the film are adduced showing the thickness at which anomalies in R and its temperature relationship disappear. A sharp maximum of R was observed close to the  $Mg_3Bi_2$  composition of the alloy, at which the film becomes transparent. During fractional

Card 1/2

137-58-6-13160

Electric Conductivity of Mg-Bi Alloys

evaporation of the metal, a maximum R appears after annealing at 230°C, but its magnitude is much lower. To establish the effect of air, measurements were taken with protective SiO coating on surface of alloys, but the character of curve did not change. The temperature relationship of R demonstrates that alloys covering a broad variety of compositions approaching  $Mg_3Bi_2$  possess semiconductive properties and impurity conductivity. An evaluation of activation energy ( $\sim 0.06$  ev) was made.

Translation from: Referativnyy zhurnal, Metallurgiya, 1958, Nr 6, p 283 (USSR)

AUTHORS: Kikoin, A.K., Fedorov, G.D.

TITLE: Thermoelectromotive Forces in Mg-Bi Alloys (Termoelektrod-vizhushchiye sily v splavakh sistemy Mg-Bi)

PERIODICAL: Tr. Ural'skogo politekhn. in-ta, 1957, Nr 72, pp 90-97

ABSTRACT: Thermoelectromotive forces  $E$  of alloys of Mg-Bi group were studied using specimens produced by Vekshinskiy's technique.  $E$  in relation to Cu was measured on films of variable composition. A coated glass plate was fastened on a special table, the displacement of which was controlled by a micrometric screw and was measured with an accuracy of up to 0.2 mm. Two Cu thermoprobes were lowered onto the plate surface. The pointed ends of the probes were semi-spheroidal in shape with  $\sim 1$  mm diam. A difference in temperature was produced between the probes by heaters consisting of nickel wire which was wound on the cylindrical part of the probe and insulated on the outside with water glass.  $E$  was measured by a PPTV-1 potentiometer to which were attached the Cu wires of a Cu-constantan thermocouple. It was established that  $E$  of pure

Card 1/2

137-58-6-13161

# Thermoelectromotive Forces in Mg-Bi Alloys

Mg and Bi films having a thickness  $l > 500$  angstrom does not depend on  $l$  and has the same value as for thick material. The Mg-Bi films studied had  $l \sim 1000$  angstrom; therefore, it is assumed that thin-film effects should not play a significant role. In Mg-Bi alloys a sharply defined maximum of  $E$  was observed, which matches the maxima of resistance and transparency (ref. RzhMet, 1958, Nr 6, abstract 13160) and corresponds to the composition of  $Mg_3Bi_2$ . All this proves that  $Mg_3Bi_2$  is an impurity semiconductor. There are anomalies in the behavior of  $E$  and in the curves of transparency and resistivity in the range of concentrations corresponding to 50 atom % Bi, which may be connected with the existence of an intermetallic compound MgBi. Bibliography: 13 references.

TITLE: Measuring the High Pressure Chamber Temperature With  
a Thermal Resistor

PERIODICAL: Izmeritel'naya tekhnika, 1959, Nr 10, pp 18-21 (USSR)

ABSTRACT: The author studied the possibility of replacing the thermo-couples by thermal resistors to measure the temperature in high pressure chambers. As the use of thermocouples requires very extensive research to calculate the effect of very high pressures on their precision, the author tentatively investigated the possibility of using Soviet produced thermal resistors of the MMT-4 type (copper-manganese) (Fig 1). The investigation of the influence of high pressure on the precision of thermal resistors at 5,000 kg/sq cm and 8,000 kg/sq cm pressure was made in two high pressure chambers. In the first chamber the temperature was 15.6, 17.3, 18.5, 24.4, 33.2 and 35.2°C at a pressure up to 5,000 kg/sq cm; in the second chamber the temperature was 17.4°C

Card 1/2

SOV/115-59-10-8/29

Measuring the High Pressure Chamber Temperature With a Thermal Resistor

at a pressure of up to 8,000 kg/sq cm. The resistance of the resistors was measured with a bridge having an error possibility of up to 0.5 ohm. Graphs 2,3 and 4 show the results of these tests. A table showing the corrections which must be introduced in the temperature indicated by a thermal resistor is given in the article. The table shows that a resistor is no more precise than a thermocouple. The high pressure chambers were constructed according to the plans prepared by M.I. Oleynik and V.A. Stepanov. There are 3 graphs, 1 diagram, 1 table and 5 references 1 of which is Soviet, 2 French, 1 American and 1 Canadian.

TITLE: Problem of the determination of physical quantities

PERIODICAL: Referativnyy zhurnal, Fizika, no. 3, 1962, 21, abstract 3A211  
(Sb. "Filos. vopr. fiz. i khimii", Sverdlovsk, 1959. 55-61)

TEXT: The variety of correlations and relationships in natural phenomena makes it possible to describe them in various ways, using different selected concepts and quantities. Therefore, it may be stated that there is a certain liberty of choice in the determination of physical quantities. In nature, only the relationships between quantities (objective laws), not the quantities themselves, are clearly defined. In this connection, many critical remarks of a philosophical character addressed to L. I. Mandel'shtam on the occasion of his lecture on the theory of relativity appear to be unfounded. ✓

The Effect of Nuclear Radiation (Cont.)

PURPOSE: This book is intended for personnel concerned with nuclear materials.

COVERAGE: This is a collection of papers presented at the Moscow Conference on the Effect of Nuclear Radiation on Materials, held December 6-10, 1960. The material reflects certain trends in the work being conducted in the Soviet scientific research organization. Some of the papers are devoted to the experimental study of the effect of neutron irradiation on reactor materials (steel, ferrous alloys, molybdenum, avial, graphite, and nichromes). Others deal with the theory of neutron irradiation effects (physico-chemical transformations, relaxation of internal stresses, internal friction) and changes in the structure and properties of various crystals. Special attention is given to the effect of intense  $\gamma$ -radiation on the electrical, magnetic, and optical properties of metals, dielectrics, and semiconductors.

TITLE: Stimulating effect of x ray and gamma irradiation on the flotation process

SOURCE: Soveshchaniye po probleme Deystviye yadernykh izlucheni na materialy. Moscow, 1960. Deystviye yadernykh izlucheni na materialy (The effect of nuclear radiation on materials); doklady soveshchaniya. Moscow, Izd-vo AN SSSR, 1962, 329-331

TOPIC TAGS: gamma irradiation, flotation, irradiation effect, x ray irradiation, pyrite, quartz, mineral coal

ABSTRACT: In the last few years, the authors have conducted experiments on flotation of monominerals (rutile, quartz, feldspar, scheelite, malachite, pyrochlore, etc.), ores, and coals irradiated with x rays,  $Co^{60}$   $\gamma$  rays, and betatron radiation with 22 MEV maximum energy of  $\gamma$  quanta. The ground material prepared for flotation was irradiated for various periods of time, after which flotation was carried out. In almost all cases, the irradiation had a stimulating effect on the flotation process, increasing its rate and improving its characteristics. Among the few substances whose flotation was adversely

Card 1/2

L 3413-66

ACCESSION NR: AT5023814

affected were quartz and feldspar. During the flotation  $\text{Co}^{60}$  radiation was very effective in increasing the rate of the process even though the dose was very low. The radiation may change the adsorption of gas on the solid-gas interface as a result of a change in the surface charge on the solid particles of the floated material. Orig. art, has: 1 figure.

TITLE: A vacuum device with a diffusion pump

SOURCE: Pribery i tekhnika eksperimenta, no. 3, 1966, 165-167

TOPIC TAGS: vacuum, vacuum chamber, vacuum pump, vacuum technology, diffusion pump

ABSTRACT: A simple vacuum device capable of producing in its evaporating chamber a vacuum of  $\sim 5 \cdot 10^{-8}$  torr, which is high enough for thin film technology, is described. Usually the possibility of obtaining such a vacuum depends on the speed with which working pressure is restored in the chamber after dismantling and parts replacement. Because of this every attempt to obtain a metallic thin film takes a long time and, if frequent replacements of the evaporator, or other parts of the vacuum device are required, then major difficulties are encountered. In the vacuum device discussed a diffusion pump, mounted directly in the evaporating chamber, is utilized which makes it possible to obtain within a short time a pressure of  $2 \cdot 10^{-7}$  and a vacuum of  $5 \cdot 10^{-8}$  torr. The evaporating chamber is in the form of a  $3\phi 250$  mm cylinder with a volume of 15 l mounted on a steel plate. The chamber is evacuated through an opening in the center of the steel plate by the RVN-10 preevacuation pump and by the TsVL-100 oil-

Card 1/2

vapor pump. High vacuum speed made possible by the diffusion pump permits the use of ordinary pressurizing and vacuum sanitation methods. The speed is such that during the evaporation with insignificant gas releases the pressure in the chamber increases by less than half an order of magnitude. Orig. art. has: 1 figure.

PROCESSES AND PROPERTIES INDEX

The magnetic moment and the number of the conducting electrons in nickel. YA. G. DORFMAN AND I. K. KIKOIN. *J. Russ. Phys.-Chem. Soc., Phys. Pt.* 61, 159-66 (1929).—A thermodynamic investigation makes it possible to find the change of the sp. heat of the conducting electrons in a ferromagnetic substance at the Curie-point through the study of the thermoelec. behavior of the substance. The ratio of the change of the sp. heat of the electrons in the metal to the sp. heat of the metal itself gives information about the role of the conducting electrons in ferromagnetism. The exptl. results obtained make it certain that the pos. ions in Ni do not play any role in ferromagnetism and that the conducting electrons only are the real elementary magnets of Ni. The numerical value of the sp. heat of the conducting electrons gives the inner quantum no. of this magnet. This result also makes it possible to find the magnetic moment of the spinning electron, which is 1 Bohr magneton. Different magnetic data when combined with the thermoelec. data, already known, lead to the conclusion that the no. of conducting electrons in Ni is a function of temp. V. VRSKLOVSKY

New Photoelectric Effect in Curpous Oxide

Nature 131, 725, 1933

KIKOIN, I. K., DORFMAN, Ia. G.

GTTI, Leningrad, 1934, 495 pp, Physics of Metals.

"A monograph."

KIKOIN, I.

3068. New Photoelectric Effect in Cuprous Oxide. I. Kikoin.  
*Comptes Rendus de l'Acad. des Sciences, U.R.S.S.* 2. 2. pp. 71-70, 1034. In  
 German.—If on a plate of  $\text{Cu}_2\text{O}$ , placed between the poles of a magnet at  
 the temperature of liquid air, light falls in a direction perpendicular to the  
 field and to the surface of the plate, then there exists in the plate in a  
 direction perpendicular to the field and to the direction of the incident  
 light a potential gradient which depends on the magnetic field. The  
 nature of the electrodes used in measuring the p. d. has no influence.  
 Further quantitative measurements show that the current due to the p. d.  
 which flows through the test piece in the magnetic field is strictly pro-  
 portional to the intensity of the incident light. If  $L$  is the intensity of the  
 light and  $H$  the field strength the current  $i = \kappa LH$  where  $\kappa$  is a material  
 constant. If  $\sigma_0$  is the thermal conductivity and  $\sigma_1$  the photo-conductivity  
 ( $\sigma_1 = \beta L$ ) then the p. d.  $V = \kappa L / (\sigma_0 + \beta L)$ . When  $L$  is large  $V = \kappa / \beta$  is  
 constant, or a saturation must be observed which agrees with experiment.

J. J. S.

Effects observed on illuminating cuprous oxide in a magnetic field. I. K. Kikoin. (Soviet Acad. Sci. U. S. S. R. 418 20 (in German 420 1) (1964); cf. C. A. 26, 6395). Measurements have been made of the cross potential difference in plates of  $\text{Cu}_2\text{O}$  supported in a magnetic field, illuminated from a direction perpendicular to the magnetic field, at different positions of rotation on an axis perpendicular to the direction of the field and to the direction of illumination. This potential difference is proportional to the square of the field strength and is a max. for a plate position of  $45^\circ$  to the direction of the field. There is also a potential difference between electrodes

placed on those opposite faces of a slab of  $\text{Cu}_2\text{O}$  that are perpendicular to the direction of illumination and parallel to the magnetic field. This potential varies directly with the field strength and is apparently caused by the diversion of electrons which diffuse from the illuminated part of the slab to the unilluminated part under the electrodes when the block is in the magnetic field. H. A. Smith

ASTM 15.4 METALLURGICAL LITERATURE CLASSIFICATION

A new photoelectric effect in cuprous oxide. I. K. Kikoin and M. M. Norkov. *Fizika* 5, 586 (1934); cf. *C. A.* 28, 1241. A thin plate of  $\text{Cu}_2\text{O}$  with electrodes in 2 opposite edges was placed between the poles of an electromagnet and one side illuminated. The plate was at liquid-air temp. A p.d. was found with magnetic field but absent without the field, and absent at room temp. Only light absorbed by the  $\text{Cu}_2\text{O}$  was effective, and red light, not absorbed, reduced the effect of blue light. The effect is explained by the existence of 2 equal but opposed currents which are influenced differently by a magnetic field. A. R. F. Duncan

<p>SA</p> <p>3849. Gyromagnetic Effect in Superconductors. I. K. Kikoin and S. V. Goebar. <i>Comptes Rendus (Doklady) de l'Acad. des Sciences, U.S.S.R.</i> 19. 4. pp. 249-251, 1938. In English.—A brief description is given of measurements of the gyromagnetic effect on superconductors, using the resonance method proposed by Kikoin. A ball of Pb is used and the current is alternated by means of a special thyatron relay; in this way the secondary effects are practically eliminated. The Einstein-de Haas effect occurs in Pb at the boiling point of liquid He in fields below the critical one and the sign is negative (as would be expected for electrons). The existence of a gyromagnetic effect is thus not due to the influence of electron inertia in eddy currents (Tolman effect) for these cannot arise in the specimens used. The results will be described in detail later.</p> <p>H. J. H. S.</p>

<p>The gyromagnetic effect in superconductors. I. K. Kikoin and S. V. Gubser. <i>J. Phys. (U. S. S. R.)</i> 3, 333-337 (1940); <i>Chem. Zvesti.</i> 1941, II, 2179.—The question of the existence of a magnetomech. effect in superconductor is of double significance. The answer would clarify whether this effect, heretofore observed only in the case of ferro- and paramagnetic substances, can occur in principle also in the case of diamagnetic substances. This would considerably enrich our as yet scanty knowledge of the essence of supercond. The Einstein-Haas effect was measured for Pb in the superconducting state, and found to be considerable. The value of the Lande <math>g</math>-factor is <math>1 \pm 0.03</math>. The magnetomech. effect is therefore due to circular currents and not to spin. In the present status of the micro-theory of supercond., the origin of these circular currents can not yet be explained satisfactorily. F. H. R.</p>

<p><i>M</i></p> <p><b>*The Temperature Dependence of the Resistance of Liquid Metals at Constant Volume.</b> S. Gulbar and I. Nikom (<i>J. Physics, U.S.S.R.</i>, 1945, 9, (1), 52-53). (In English.) It is pointed out that the theory of electrical conductivity applies to constant volume, whereas experimental measurements are usually made at constant pressure. The difference between the temperature coeffs. of resistance at constant pressure and constant volume is important for liquid metals, where volume expansion coeffs. are high. Measurements of the temperature coeffs. of liquid metals may be made by enclosing the liquid inside a thick walled capillary of glass; once the metal has filled the available space, its volume increases only at the expense of the expansion and deformation of the glass, and conditions approximate to constant volume. Under these conditions, mercury shows a very small temperature coeff., if correction is made for expansion of the glass, the coeff. becomes negative. It is mentioned that, by choosing an appropriate type of glass, the resistance of the enclosed mercury thread may be made constant over a range of temperature, thus providing a standard resistance. - G. ( $2\pi/\delta$ )  $\ln(2l/l_0)/\delta A$ , where  $\delta$  = logarithmic decrement,  $l$  = period,  $l_0$  = distance of magnetic field,  $A$  = magnetic amplitude,  $d$  = diam. of the sample sphere. For superconductivity,  $d = 3.708 \times 0.003$  mm,  $\delta A = 0.005 \times 10^{-6}$ ,  $l = 1$  cm,  $\ln(2l/l_0) = 4.12$  sec.,  $\delta/l = 0.31 \times 10^{-6}$ ,  $l = 24.7$ ,  $g = 1 \pm 0.03$ . This value of  $g$  corresponds to dia-  
magnetic magnetization due to closed orbits; the aver-  
aged neg. sign of  $g$  corresponds to neg. currents (ch-  
trons). Rejection of possible sources of error shows  
that hysteretic giving rise to irreversible magnetization  
cannot, in superconductors, have an effect in fields of  
about 150 oersteds as used; that there could be no freezing  
of the field within the sample, owing to the order  
of the field with respect to asymmetry of the field of the order  
of  $0.1\%$  is negligible, and so are the remaining errors due  
to incomplete compensation of the slit, etc. In conclusion, the  
asymmetry with regard to the slit, etc. In conclusion, the  
existence of diamagnetic effects in diamagnetic super-  
conductors, is demonstrated; the magnetization of super-  
conductors is not dectd. by electron spin but by closed-  
current circuits that may be either atomic or microscopic.  
Interpretation of the latter as Penzance penetration of the  
field into the superconductor. No interpretation can be  
given at this stage of microscopic (atomic) circuits.  
S. Thon

 TITLE On the Transversal Photomagnetic Effect in n - and p - Germanium.  
 PERIODICAL Dokl.Akad.Nauk, 109, fasc.4, 735-736 (1956)  
 Issued: 10 / 1956 reviewed: 10 / 1956

In connection with the usual photomagnetic effect a field strength which is proportional to the field strength  $H$  occurs in the case of illumination along the Y-axis of a sample arranged in a magnetic field (having the direction of the X-axis) in the direction of the Z-axis. If, however, the magnetic field, apart from the component  $H_x$ , also has the component  $H_y$ , an electromotoric force which is proportional to the product  $H_x H_y$  occurs additionally in the X-axis, and this is the transversal photomagnetic effect.

The experimental order is discussed in short. The sample under investigation, which has the shape of a plane rectangular plate, must be fixed at an angle  $\alpha$  with respect to the direction of the magnetic field. The samples consisted of plane plates of the size 12 x 6 x 0,8 (mm ?) and were cut out from a germanium monocrystal. The specific resistance of the samples was  $45 \Omega \cdot \text{cm}$  in the case of p-germanium and  $40 \Omega \cdot \text{cm}$  in the case of n-germanium. The samples were mounted in a glass tube on a ground carrier (slide) and the tubes with the samples were arranged between the poles of a large electromagnet. By rotating the ground carrier (slide) round its axis it was possible to modify the angle between the plane of the sample and the direction of the magnetic field. As expected, the transversal electromotoric force at  $\alpha = 0$  was equal to zero, and at  $\alpha = 45^\circ$  it

Dokl.Akad.Nauk, 109, fasc.4, 735-736 (1956) CARD 2 / 2

PA - 1434

attained its maximum value. A peculiar feature is the dependence of the transversal photoelectromotoric force on field strength. In the case of low field strengths this  $E$ , as may be expected, is proportional to  $H^2$ . In the case of strong fields this dependence is essentially influenced by the temperature of the sample. At room temperature the electromotoric force increases monotonously with an increase of field strength. However, at lower temperatures it attains a maximum, passes through zero, and finally changes its sign. If the direction of the magnetic field changes, the sign of the transversal electromotoric force is conserved in any case. The magnetic field strength that corresponds to the maximum electromotoric force diminishes with a decrease of temperature. Therefore the temperature dependence of the transversal photomagnetic effect was investigated. In the case of p-germanium the transversal photomagnetic electromotoric force changes its sign twice, on which occasion it passes through a maximum. In the case of n-germanium no change of signs was found to occur in the temperature range investigated. The transversal photomagnetic effect is apparently produced by deflection of the current carriers moving in the direction of the photomagnetic electromotoric force.

TITLE: On the Transverse Photomagnetic Effect in n- and p-Germanium  
(O poperechnom fotomagnitnom effekte v n- i p-germanii)

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Fizicheskaya, 1957,  
Vol. 21, # 6, p 801 (USSR)

ABSTRACT: The so-called transverse photomagnetic effect was investigated in single crystals of germanium. This effect, which arises in semiconductors during their illumination in a magnetic field, is proportional to the square of the field intensity and depends on the angle between the normal to the plane of a sample and the magnetic field direction.

A dependence of the transverse photomagnetic e.m.f. on the magnetic field and the temperature was established.

It was shown that in p-germanium the transverse photomagnetic e.m.f. reverses its sign at sufficiently intensive fields.

TITLE: On the Anisotropy of the Even (Transverse) Photomagnetic Effect in Germanium Monocrystals (Ob anizotropii четного (поперечного) фотомagnetного эффекта в монокристаллах германия)

PERIODICAL: Doklady AN SSSR, 1957, Vol. 116, Nr 3, pp. 361 - 364 (USSR)

ABSTRACT: The author showed in two preliminary studies (ref. Nr 1 and 2) that within semiconductors besides the ordinary photomagnetic effect still another photomagnetic effect exists. This other effect has been called a transverse photomagnetic effect. This effect consists of the following: With an illumination of the sample (a plane plate, arranged in a magnetic field, whereby the direction of the magnetic field includes a certain angle with the direction of the plate-plane) there appears in it an electric field (and a corresponding potential difference) which is directed vertical to the electric field of the ordinary photomagnetic effect. The difference of the potentials of the "transverse" photomagnetic effect does not modify the sign with the reversal of the field direction. Therefore it is more practical to call this effect further the even photomagnetic effect. The equation  $V_s = AH^2 \sin 2\alpha$  applies to the potential difference caused by that even photomagnetic effect. Here de-

Card 1/3

On the Anisotropy of the Even (Transverse) Photomagnetic Effect in Germanium Monocrystals

note - H the magnetic field strength,  $\alpha$  - the angle between the direction of the field H and the plane of the sample, A - the coefficient which depends on the light intensity, or the characteristics of the sample, on the condition of the surface, etc. The examination of this effect showed the following: It concerns a kind of Hall - (Khol) - effect which is produced by an odd photomagnetic current. In germanium monocrystals the even photomagnetic effect is in many circumstances different from that, observed in polycrystalline copper oxydide. The angle dependence  $V_s = AH^2 \sin 2\alpha$  does not apply to monocrystals. The experimentally obtained angle dependence for germanium monocrystals is here shown in a diagram. Such a strong angle dependence only can be defined by assumption of an essential anisotropy of the effect. Therefore the authors investigate the anisotropy of the even photomagnetic effect. Practically round targets are used for the investigation. The teeth cut out of the target served as electrodes. These samples were brought into a magnetic field and irradiated in vertical direction to this field. The carrying out of the experiment manifested an essential dependence of the potential difference on the angle  $\varphi$ . Here this dependence for a sample of n-germanium is demonstrated in a diagram. There is obviously no simple correlation between the

TITLE: Test Reactor With Gaseous Fissile Material ( $UF_6$ ) (Stendovyy  
reaktor s gazoobraznym delyashchimaya veshestvom ( $UF_6$ ))

PERIODICAL: Atomnaya energiya, 1958, Vol. 5, Nr 4, pp. 294-302 (USSR)

ABSTRACT: The reactor is of the heterogeneous type, the moderator consists of metallic beryllium (1570 kg), and graphite is used as a reflector. The beryllium was available in form of cubes the edges of which had a length of 40 mm. The active zone is a cylinder of 1160 mm diameter and 1080 mm height. The gaseous (not enriched) uranium hexafluoride filled 168 channels which were arranged in form of a quadratic lattice with a spacing of 80 mm. The channels consisted of quadratic aluminum tubes of 40 . 40 . 1 mm. 4, 8, 10, 12, and 14 channels are arranged in a row, one beside the other. The working volume of a channel within the domain of the active zone is 1440 cm<sup>3</sup>. The total volume of the active zone is 214 l. The lateral graphite reflector has a thickness of 500 mm, while the thickness of the

Card 1/3

A Test Reactor With Gaseous Fissile Material ( $UF_6$ )

DOV 69-117 15

upper and lower reflectors is 600 mm. 12 channels of 12 mm diameter pass through the upper reflector; this makes it possible to feed the active zone with gas. 12 horizontal and 12 vertical channels are provided for regulation and shut-off. The reactor can be heated from the outside by means of an electrical aggregate of 35 kW. Heating the reactor up to a temperature of 80 - 90°C takes 10 - 15 hours. The reactor is located in a steel casing of 2500 mm diameter, which can be hermetically sealed. Rubber gaskets are used for sealing. The system for the blowing-in and -out of gas consists of a receiver for uranium-hexafluoride, emergency cistern, a measuring apparatus, and remote-controlled valves. Reactor control is carried out by hand. The regulating rods are steel tubes with a diameter of 22 and 9 mm, which are filled with boron carbide. In August 1957 the reactor became critical for the first time. The quantity of gas amounting to 5.540 ± 40 g  $UF_6$ . The maximum power output hitherto attained due to the biological stability of 1.5 kW. With this power output a neutron flux of  $1.1 \cdot 10^{12}$  neutrons/cm<sup>2</sup> was measured in the center of the reactor. The radial distribution of the thermal neutron flux was measured and

Cont. 2

A Test Reactor With Gaseous Fissile Material ( $UF_6$ )

SOV/89-5-3-8/15

plotted. For the reactivity  $\rho$  the value

$$\rho = 1,35 \cdot 10^{-4} \Delta m g$$

was found. The dependence  $\rho(\tau)$  is plotted ( $\tau$  denotes the time within which the neutron flux increases up to e-fold its amount). The temperature coefficient was measured and shown in form of a graph. The dissociation rate of the molecules  $UF_6$  was determined as amounting to 0,32 mol/kWh. The addition of chlorotrifluoride shows that working conditions can be found in which stability or radiation of the uranium-hexafluoride in the reactor can be attained. A. M. Susova assisted in assembling the apparatus in collaboration with A. A. Krasin. There are 12 figures and 3 references, 1 of which is Soviet.

TITLE: On the Anomalously High Hall-effect in the Ferromagnetic Alloy Chromium-tellurium (Ob anomal'no bol'shom effekte Kholla v ferromagnitnom splave khrom-tellur)

PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 125, Nr 5, pp 1011-1014 (USSR)

ABSTRACT: In the investigation of the galvanomagnetic effects in ferromagnetic alloys consisting of non-ferromagnetic components, the authors observed an anomalously high ferromagnetic Hall-coefficient in the alloy chromium-tellurium (50 atom %). By ferromagnetic Hall-coefficient the authors mean the amount of the coefficient  $R_J$  defined by the equation

$$\vec{E} = R_J [\vec{j} \times \vec{j}] + R_O [\vec{H} \times \vec{j}]$$
. To this equation there corresponds the equation  $U_H = R_J j \frac{1}{d} + R_O H \frac{1}{d}$ . Here  $\vec{E}$  denotes the electric field strength,  $U$  - the potential difference corresponding to it, which occurs in the sample with the amperage  $\vec{j}$  under the

Card 1/4

On the Anomalously High Hall-effect in the  
Ferromagnetic Alloy Chromium-tellurium

SOV/20-125-5-16/61

influence of a transversal magnetic field  $\vec{H}$  and the corresponding magnetization  $\vec{J}$ ,  $d$  - the thickness of the sample,  $R_0$  - the "classical" Hall coefficient. For ordinary (non-ferromagnetic) metals the first term of the right sides of the two equations written down above are equal to zero. For the theory of galvanomagnetic effects investigation of each of the two coefficients  $R_J$  and  $R_0$  is of interest. In the present paper attention is concentrated upon  $R_J$ . In a table the value of  $R_J$  of the above mentioned chromium-tellurium alloy is compared with the value of this coefficient for other ferromagnetics. In view of the temperature dependence of  $R_J$  the comparison is carried out for equal values of the reduced temperature  $T/\theta$ , where  $\theta$  denotes Curie temperature. For the above mentioned alloy it holds that  $\theta = 54^\circ$  (according to measurement of the magnetocaloric effect). As far as the authors know such a high ferromagnetic Hall coefficient (100 times as high as in the case of iron) is observed for the first time. Particular interest is caused by the temperature dependence of the Hall

Card 2/4

On the Anomalously High Hall-effect in the  
Ferromagnetic Alloy Chromium-tellurium

SOV/20-125-5-16/61

effect and especially by its measurement when passing through the Curie point. The relatively low Curie temperature and the high Hall effect render the here investigated alloy especially suited for such investigations. The authors therefore investigate the temperature dependence of the Hall effect in the alloy Cr-Te below as well as above Curie point. (From the temperature of liquid nitrogen to 300°). The present paper describes the most important results obtained firstly with respect to the Hall effect below Curie point. A diagram shows the dependence of the difference of Hall potentials  $U_{Hi}^d$  on the magnetic field strength  $H$  at various temperatures.  $R_J$  is directly connected with the square  $J_{sp}^2$  of spontaneous magnetization. The observed temperature dependence of  $R_J$  is probably due to the temperature dependence of the spontaneous magnetization  $J_{sp}$ . It holds that  $R_J = a(\beta - J_{sp}^2)$ . The constant  $\beta$  agrees with sufficient accuracy with  $J_0^2$ , the

Card 3/4

On the Anomalously High Hall-effect in the  
Ferromagnetic Alloy Chromium-tellurium

SOV/20-125-5-16/61

square of spontaneous magnetization at absolute zero. Thus, it holds that  $R_J = a(J_o^2 - J_{sp}^2)$ . Above Curie point the difference  $U_H$  of Hall's potentials is proportional to the magnetic field strength and also in the ordinary metals:  $U_H = RH \frac{1}{d}$ . The authors in the aforementioned alloy check the correctness of the previously found relation (Ref 7)  $U_H = R_p \chi H \frac{1}{d} + R_1 H \frac{1}{d}$  or  $R = R_p \chi + R_1$ . Here  $\chi$  denotes magnetic susceptibility and  $R_p$  the paramagnetic Hall-coefficient. The "paramagnetic" component of the Hall coefficient actually obeys the Curie-Weiss law. There are 4 figures, 1 table, and 7 references, 3 of which are Soviet.

TITLE: Galvanomagnetic Phenomena in the Ferromagnetic Alloy MnSb

PERIODICAL: Fizika metallov i metallovezeniy, 1960. Vol. 10.  
No. 3, pp. 488 - 490

TEXT: It is said that no satisfactory theory of galvanomagnetic effects in ferromagnetics is available at the present time. This is largely due to the lack of experimental data in this important field. The present authors have investigated the temperature dependence of the Hall coefficient and the electrical resistivity of MnSb alloys (50 at.%). The same specimens were used to measure the temperature dependence of the magnetisation curves and the magnetocaloric effect. Fig. 1 shows the ferromagnetic Hall coefficient  $R_J$  as a function of the square of the spontaneous magnetisation (the units of  $R_J$  are V g/amp gauss cm<sup>2</sup> and the units of

Card 1/4

Galvanomagnetic Phenomena in the Ferromagnetic Alloy MnSb

$\sigma_s^2$  are gauss<sup>2</sup>cm<sup>6</sup>/g<sup>2</sup>). If  $R_J$  is represented by a formula of the form

$$R_J = a(\sigma_0^2 - \sigma_s^2) \quad (2)$$

then it is found that  $\sigma_0 = 111.76$  gauss/cm<sup>3</sup>/g. It is known (Kikoin et al, Ref. 1) that a similar formula holds for chromium-tellurium alloys. Eq. (2) can also be derived from the theory of galvanomagnetic effects in ferromagnetics as given by Vonsovskiy et al (Ref. 2) and Patrakhin (Ref. 3). The equation can be used to establish a relation between the ferromagnetic Hall coefficient and the electrical resistivity  $\rho$ . This relation differs from the Karplus--Luttinger (Ref. 4) relation

$$R_J = A \rho^2 \quad (3)$$

Card 2/4

Galvanomagnetic Phenomena in the Ferromagnetic Alloy MnSb

which does not agree with experiment. The present authors use the relation

$$R_j = \alpha - \beta \Delta \rho \quad (5)$$

where  $\Delta \rho$  is the ferromagnetic part of the resistivity. An experimental plot of  $R_j$  versus  $\Delta \rho$  is shown in Fig. 2.

Agreement with Eq. (5) is seen to be satisfactory. A more detailed description of experiments and results will be published later. There are 2 figures and 5 references: 3 Soviet and 2 non-Soviet.

TITLE: Anisotropy of the Even Photomagnetic Effect in n-Type Germanium at Low Temperatures

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1960, Vol. 39, No. 5(11), pp. 1471 - 1473

TEXT: At room temperature the anisotropy of the even photomagnetic effect in germanium can be described fairly well with phenomenological equations of Yu. Kagan and Ya. A. Smorodinskiy in a field up to 20,000 oe but an investigation of the temperature dependence of the even photomagnetic effect at low temperatures showed that its anisotropy runs in an anomalous manner. The present "Letter to the Editor" reports about such investigations on an n-type germanium single crystal. The spherical sample was arranged so that the [111] axis coincided with the normal  $\vec{n}$  of the irradiated surface. The field direction  $\vec{H}$ , the exposure direction, and the direction where the even photomagnetic e.m.f. was measured corresponded to the coordinate directions x,y,z. In the z-direction,

besides an even, also an odd photomagnetic e.m.f. occurred which could be excluded by measuring in two different  $\vec{H}$ -directions. This even photomagnetic e.m.f. ( $E_q$ ) can be described through the above mentioned phenomenological equation as

$$E_q = \frac{1}{3\sqrt{2}} LH^2 \sin^2 \theta \cos 3\varphi, \text{ where } \varphi \text{ is the angle of rotation of the sample}$$

about  $\vec{n}$ ,  $\theta$  is the angle between  $\vec{n}$  and z, L is a material constant. The sample was rotated about  $\vec{n}$  and also about z (in order to change  $\varphi$  and  $\theta$ ). The formula describes quite well the experimental results as obtained at nitrogen temperature and at room temperature for the  $\varphi$  dependence of the even photomagnetic e.m.f. The  $\theta$  dependence at 78°K is entirely different from that at room temperature. This dependence is illustrated in Fig.1. The extreme values of  $E_q$  are plotted on the ordinate and correspond to the values  $\varphi = \pi/3, 2\pi/3, \dots$ . Fig. 2 shows  $E_q$  as a function of H at various  $\theta$ .

There are 2 figures and 4 Soviet references.
